Abstract	Our sense of presence in the real world helps regulate our behaviour within it by telling us about the status and effectiveness of our actions. As such, this ability offers us practical advantages in dealing effectively with the world. It is also an automatic or intuitive response to where and how we find ourselves in that it does not require conscious thought or deliberation. In contrast, the experience of presence or immersion in a movie, game or virtual environment is not automatic but is the product of our deliberate engagement with it, an engagement which first requires a disengagement or decoupling with the real world. Of course, we regularly decouple from the real world and embrace other, possible worlds every time we daydream, or engage in creative problem solving or, most importantly, for the purposes of this discussion, when we <i>make-believe</i> . We propose that make-believe is a plausible psychological mechanism which underpins the experience of mediated presence.

6 **Abstract** Our sense of presence in the real world helps  
7 regulate our behaviour within it by telling us about the  
8 status and effectiveness of our actions. As such, this ability  
9 offers us practical advantages in dealing effectively with  
10 the world. It is also an automatic or intuitive response to  
11 where and how we find ourselves in that it does not require  
12 conscious thought or deliberation. In contrast, the experi-  
13 ence of presence or immersion in a movie, game or virtual  
14 environment is not automatic but is the product of our  
15 deliberate engagement with it, an engagement which first  
16 requires a disengagement or decoupling with the real  
17 world. Of course, we regularly decouple from the real  
18 world and embrace other, possible worlds every time we  
19 daydream, or engage in creative problem solving or, most  
20 importantly, for the purposes of this discussion, when we  
21 *make-believe*. We propose that make-believe is a plausible  
22 psychological mechanism which underpins the experience  
23 of mediated presence.

26 Engagement · Immersion

27 **1 Introduction**

28 Presence, as an academic discipline, dates from the early  
29 1990s with the publication of the first journal dedicated to  
30 its research. This is not to suggest, however, that designers,  
31 artists and writers have been unaware of the power of their  
32 media to create a sense of immersion or transportation or

feelings of being present elsewhere, from long before this 33  
time. Prehistoric cave art may have been created for this 34  
very purpose, and the use of stained glass in churches and 35  
cathedrals has been recognised as a means of transporting 36  
churchgoers to higher, spiritual dimensions. Indeed stories 37  
of all kinds, irrespective of medium, have this power to 38  
transport, immerse, engage and to create a sense of being 39  
other than where we currently are. The English romantic 40  
poet Samuel Taylor Coleridge coined the term, “the will- 41  
ing suspension of disbelief” to describe the apparent 42  
willingness of readers to engage with stories irrespective of 43  
their credibility. (Though we are mindful of the earlier and 44  
more sober observations of the David Hume who wrote of 45  
*imaginative resistance*, that is, the reluctance we feel when 46  
we are invited to embrace something unbelievable.) 47

So, before considering what others have defined as 48  
presence, just what is our central question? It is this, what 49  
is it that a cave painting, a stained glass window, a poem 50  
and a myriad of digital technology have in common? A 51  
tempting answer might lie with inverting Coleridge’s “the 52  
willing suspension of disbelief” from a double negative to 53  
the positive statement, “the willingness to believe”. 54  
However, even if we emphasise the temporary nature of 55  
this belief, *belief*, in itself, is much too powerful a claim. 56  
When we watch a (fictional) movie we do not believe what 57  
we see, nor do we suspend disbelief instead *we act (think* 58  
*and feel) as though* what we are engaged with were the 59  
case. 60

So, returning to the examples we have already consid- 61  
ered, we do not propose that the people who first gazed on 62  
cave paintings actually believed themselves to be in the 63  
presence of aurochs nor, while in churches, to be in the 64  
company of spiritual beings. Neither do we propose that 65  
people believe themselves transported to a “stately plea- 66  
sure dome” after reading Kublai Khan nor fighting aliens 67

68 on the surface of Mars with their space marine buddies in a  
69 games arcade. What we *do* propose is that people readily  
70 act, think, react and emote as though we were or might be  
71 in these situations.

72 This “as if”, “as though” and “might be” indirection is  
73 one of the key differences between believing and making-  
74 believe (and as we shall see, the difference between sanity  
75 and psychosis). So rather than believing that we are else-  
76 where, we propose that we make-believe that we are.

77 The power of make-believe is not to be underestimated.  
78 It is astonishingly ubiquitous and can be found at work in  
79 everything from the kind of mundane “what if” thinking  
80 we might engage in when deciding what to have for dinner,  
81 through to scientific reasoning (e.g. Einstein famously  
82 imagined himself chasing a light beam) or competing in the  
83 world “air guitar” championships (Guitar 2014). Carru-  
84 thers (2011) has also argued that these forms of adult  
85 creative expression and childhood pretend play share  
86 common cognitive resources/origin; indeed, Vygotski  
87 (1978) argued that imagination is “internalised” pretend  
88 play. Further, this form of thinking may be a relatively  
89 recent evolutionary development which may have first  
90 appeared some 50,000 years ago and is responsible for the  
91 flowering of human creative thought which has continued  
92 ever since then.

93 This paper seeks to make a case for the role of make-  
94 believe in the experience of presence. So let us begin by  
95 considering the experience of presence.

## 96 2 Defining presence

97 Early, formal definitions of telepresence, that is, the sense  
98 of presence created by technology have included, “the  
99 sense of ‘being there’” (e.g. Held and Durlach 1992;  
100 Sheridan 1992); and famously as “the perceptual illusion  
101 of non-mediation” (Lombard and Ditton 1997) who wrote  
102 that, “An illusion of non-mediation occurs when a person  
103 fails to perceive or acknowledge the existence of a medium  
104 in his/her communication environment and responds as he/  
105 she would if the medium were not there”. This description  
106 is highly reminiscent of both Norman’s (1999) *disap-*  
107 *pearing computer* design proposal and Heidegger’s obser-  
108 vation that when we are absorbed in activities such as  
109 hammering, the hammer and the nails disappear and only  
110 the hammering remains (Heidegger 1927).

111 Presence has also been described as, “A mental state in  
112 which a user feels physically present within the computer-  
113 mediated environment” (Draper et al. 1998) and “the  
114 subjective experience of being in one place or environ-  
115 ment, even when one is physically situated in another”  
116 (e.g. Witmer and Singer 1998). Further and following  
117 Coleridge, Slater et al. (1994) have described presence as

“the (suspension of dis-) belief” of being located in a 118  
world other than the physical one”. As Riva (2009) notes, 119  
these accounts explicitly define presence as a consequence 120  
of using or interacting with the technology. This assump- 121  
tion, explicit or otherwise, also serves to define real world 122  
presence as the standard against which instances of this 123  
technologically mediated presence (*mediated presence* 124  
hereafter) can be compared. 125

### 2.1 Theoretically rich accounts of presence 126

More recently, these early definitions have been challenged 127  
by more sophisticated and theoretically rich treatments. 128  
These are, of course, correspondingly much longer and 129  
more detailed than the initial, rather snappy, one line def- 130  
initions. For this reason, we will focus on only one of these 131  
and here the work of Riva and Waterworth is an obvious 132  
choice as it offers a particularly detailed and complex 133  
account. They began by posing the question “What is the 134  
purpose of presence?” and have systematically answered it 135  
from a series of evolutionary-psychological, neuro-psy- 136  
chological and cognitive scientific perspectives. They 137  
argue that presence either evolved for no particular purpose 138  
(that is, as an emergent or serendipitous property of the 139  
nervous system) *or* it must offer evolutionary advantage. In 140  
examining the latter alternative, they note that “the 141  
appearance of the sense of presence allows the nervous 142  
system to solve a key problem for its survival: how to 143  
differentiate between internal and external states” (Riva 144  
et al. 2004). 145

From there, they have drawn upon neuropsychology to 146  
propose a mapping between the different forms of self or 147  
“layers” of consciousness which Damasio’s work has 148  
uncovered and corresponding forms of presence (Damasio 149  
1999). They have successively paired *proto*-presence, *core*- 150  
presence and *extended* presence onto the *proto*-self, *core*- 151  
self and *extended* self. With each step up this phylogenetic 152  
“ladder”, the experience of presence becomes richer, more 153  
detailed and more recognisable. From here, they recognise 154  
that the experience of presence is intuitive, that is, the 155  
product of unconscious and largely automatic cognitive 156  
processes. Thus, we do not make a conscious decision to be 157  
present in the world but find ourselves here as an imme- 158  
diate cognitive response. In recognising presence as an 159  
intuitive process, they also locate it within the dual-process 160  
accounts of cognition. These dual-process accounts com- 161  
prise a broad family of theories which, while disagreeing in 162  
detail, do recognise that there are two basic forms of 163  
thinking, one is fast and intuitive (usually described as type 164  
or system 1 thinking) while the other is slow and deliberate 165  
(system 2 thinking). (We return to this point in Sect. 4). 166  
Most recently, they have added the dimension of embodi- 167  
ment into their account which seamlessly affords the 168

- 169 integration of tools into the body schemata. The inclusion  
 170 of activity theory also allows us to consider presence from  
 171 the perspective of (human) objectives and goals (e.g. Riva  
 172 2009; Riva et al. 2009; Riva and Waterworth 2014).  
 173 In all, Riva and his colleagues have a comprehensive  
 174 and coherent account of real world presence. Their work  
 175 has located real world presence in a plausible evolutionary  
 176 context and mapped expression of presence to different  
 177 layers (self) of consciousness. This is a singular achieve-  
 178 ment. Other approaches have their own strengths and  
 179 weaknesses but this work provides a flavour and overview  
 180 of contemporary thinking in the presence of research. So  
 181 far we have only really considered real world presence, but  
 182 what of the technologically mediated variety?
- 183 2.2 A make-believe account of presence
- 184 We are present in the real world but we also frequently  
 185 decide to immerse ourselves and to feel present in  
 186 media. We will argue that the means by which we feel  
 187 present in these other “worlds” lies with our ability to  
 188 make-believe. When we pretend (particularly as chil-  
 189 dren), we make-believe or imagine we enter alternate  
 190 worlds. These worlds may be not as vivid, immediate or  
 191 as tangible as the real world, but they can be very  
 192 engaging. These worlds are often solely the product of  
 193 these abilities but very often they are directed and  
 194 shaped by external media and artefacts such as toys,  
 195 stories, other people and, of course, digital technology  
 196 (Walton 1990).  
 197 These episodes of mediated presence/make-believe are a  
 198 consequence of cognitive decoupling and are “sandbox-  
 199 ed”—or equivalent, in that they are labelled as make-  
 200 believe. When we stop pretending we return to the real  
 201 world. (*Before we develop this argument further, we should*  
 202 *emphasise that we not are suggesting that pretending is in*  
 203 *any sense concerned with deception or the wilful duping of*  
 204 *innocent researchers*).  
 205 Let us consider the following two scenarios. The first of  
 206 these is set in a children’s tea party while the second  
 207 considers the exploration of a virtual recreation of central  
 208 London. In the first instance:
- 209 A child proposes that she and her friends might hold a  
 210 tea party. They agree to participate and equip them-  
 211 selves with toy tea cups and a toy teapot. The teapot  
 212 is filled with water in lieu of tea. The children lay the  
 213 tea set neatly on a tablecloth. One child acting as  
 214 “mother” (the tea pourer) pours everyone a cup of  
 215 “tea”. As each child drinks from their cup of “tea”,  
 216 they may then chat and perhaps share pretend  
 217 “cake”. As the “tea” is drunk, “mother” refills the  
 218 empty cups. The party reaches its natural conclusion.
- For the duration of the tea party, the group of children  
 have made-believe that water is tea, and they have behaved  
 as if they were adults by imitating how they have seen their  
 parents behave at a real tea party. Cups have been drunk  
 from emptied and refilled. Conversations were enjoyed,  
 and “cake” may have been consumed. Having behaved as  
 if they were at a tea party, the children disperse.
- In the second instance:
- A potential tourist using an immersive re-creation of  
 London to get a sense of the city before booking a trip  
 there. The tourist, in the immersive suite of the travel  
 agent’s premises, puts on a lightweight head-mounted  
 display and a set of headphones and instantly finds  
 themselves standing at the heart of Trafalgar Square.  
 Looking around them they see pigeons completing a  
 circuit around Nelson’s Column before they head  
 down Whitehall towards the river. The potential  
 tourist is a little disappointed to find that it is not  
 raining in London but is convinced enough that they  
 want to go there in person.
- For the duration of their trip to London, this tourist has  
 made-believe that he has engaged with a faithful repre-  
 sentation of the city. They have made-believed what they  
 have seen and, within the constraints of the technology,  
 they have acted as through they were there.
- While there are enormous differences between toy tea-  
 cups and water in the first scenario and a head-mounted  
 display and a virtual model of London, there are also  
 striking parallels too. In both instances, the “players”  
 decoupled the real world in favour of a make-believe  
 world. They act as they were engaged in a tea party and as  
 though they were in Trafalgar Square. While make-believe  
 (or its synonyms) may not be the only psychological  
 mechanism involved in mediated presence it is nonetheless  
 central to its experience.
- 3 The anatomy of make-believe**
- We all pretend. We develop this ability early in life and  
 subsequently exercise it along with making-believe and  
 imagining. These activities are probably at their most  
 compelling when they are exercised in conjunction with  
 external artefacts such as toys, books and works of art or  
 more recently with digital technology.
- Pretending is important to the social and cognitive  
 development of children through its expression as (pretend)  
 play. Russ (2004), for example, has argued that the  
 development of a number of cognitive and affective pro-  
 cesses rely on pretend play. Pretend play involves the  
 exercise of divergent and convergent thinking, and it also  
 facilitates the expression of both positive and negative

- 268 feelings, and the ability to integrate emotion with cognition  
 269 (e.g. Jent et al. 2011; Seja and Russ 1999). Early pretend  
 270 play has also been implicated in creativity in later life  
 271 (Russ 2004; Singer and Singer 2005). Significantly, Garvey  
 272 (1990) tell us that pretend play is the “voluntary transfor-  
 273 mation of the here and now, the you and me, and the this or  
 274 that, along with any potential action that these components  
 275 of a situation might have”.
- 276 Pretending is purposive, and Rakoczy et al. (2004) have  
 277 reported that children as young as two are able to appre-  
 278 ciate the difference between trying to perform an action in  
 279 the real world, and pretending to perform the same action.  
 280 This ability is essential; otherwise, we would be unable to  
 281 discriminate pretending from any other form of action.  
 282 Examples of pretending are myriad but citing children’s tea  
 283 party remains a firm favourite.
- 284 So, returning to the tea party in a little more detail: once  
 285 embarked on this pretend play, the individual child makes  
 286 attributions such as, “I am drinking tea with my friends”  
 287 and this is one of many instance which are not the case.  
 288 Further, her friends are making similar attributions of  
 289 themselves and they are also each attributing the mental  
 290 state of “we are having a tea party” to each other. We note  
 291 that these mechanisms (and attributions) are examples of  
 292 social intentionality in action which is a necessary condi-  
 293 tion for *social* presence.
- 294 Adult pretending is little different. Some of us are all too  
 295 readily transported to the battles fought in Middle Earth  
 296 (Green 2005) or are happy to pretend that we can fly to  
 297 other planets and speak to the aliens we find there. Just as  
 298 the tea was not real, nor is Middle Earth and faster than  
 299 light travel is even less likely than being able to speak to  
 300 aliens. Nonetheless, we readily make-believe these things,  
 301 which are *not* the case, at least for duration of our pretence,  
 302 TV episode or scientific discussion.
- 303 Thus, pretending is the ability to engage in *what if*  
 304 thinking and as a consequence and, in short, the ability to  
 305 run mental *simulations*. Pretending as *what if* thinking is  
 306 evidenced in domains as diverse as design thinking (e.g.  
 307 Buchanan 1992), scientific reasoning (e.g. Toon 2010),  
 308 acting on stage (Goldstein and Bloom 2011) and our propen-  
 309 sity to anthropomorphise technology (e.g. Fogg and  
 310 Nass 1997).
- 311 Finally, from an evolutionary psychology perspective,  
 312 Cosmides and Tooby (2000) tell us that being able to  
 313 pretend is the result of cognitive de-coupling which they  
 314 define as our ability to make use of contingent information  
 315 and the artefacts which embody that information. They  
 316 write, “arguably, one central and distinguishing innovation  
 317 in human evolution has been the dramatic increase in the  
 318 use of contingent information for the regulation of improv-  
 319 ised behaviour” (p. 53). Thus, we pretend when presented  
 320 with media such diverse as cave art to the latest Imax  
 movie and in doing so temporarily divorce ourselves from  
 the everyday and mundane.
- ### 3.1 The curious nature of pretend play 323
- The existing research into our ability to pretend has been  
 largely confined to the study of pretend play in young  
 children. Indeed, Nichols and Stich (2005, p. 20) have  
 commented on the paucity of research into adult pretend-  
 ing. However, from their own work, they conclude that  
 adult and childhood pretending is not very different. While  
 this judgement may be a little broad, there is no extant  
 evidence to the contrary.
- It should be noted that the primary focus of these studies  
 has tended to be the nature and dynamics of pretend play  
 and its role in the cognitive or social development of the  
 child. However, children’s ability to pretend *per se* has also  
 received attention.
- Pretending (and pretend play) presents a number of  
 intriguing, if not downright astonishing, problems for the  
 researcher as identified by Leslie (1987, p. 412), “Pre-  
 tending ought to strike the cognitive psychologist as a very  
 odd sort of ability. After all, from an evolutionary point of  
 view, there ought to be a high premium on the veridicality  
 of cognitive processes. The perceiving, thinking organism  
 ought, as far as possible, to get things right. Yet pretence  
 flies in the face of this fundamental principle. In pretence,  
 we deliberately distort reality”. In essence, we can pretend  
 before we have formed a veridical view of the world. He  
 continues with the observation that our ability to pretend  
 should, more reasonably, arise at the end of our intellectual  
 development rather than “at the very beginning of child-  
 hood”. Most recently, Nakayama (2013) has presented  
 evidence of children as young as 7 months old pretending  
 to cry merely as a means of obtaining “caregiver physical  
 contact”. There is widely accepted evidence that children  
 are able to engage in pretending soon after their first  
 birthday, and this is years earlier than any suggestion of a  
 fully developed cognition. Having achieved cognitive  
 mastery of the world, one might expect an individual to be  
 able to demonstrate this ability by deliberately distorting  
 the representation and then returning to it skilfully, but not  
 before complete competence had been acquired. Finally, in  
 a form of language which is reminiscent of computer sci-  
 ence, Leslie poses the following questions just how is it  
 possible for a child to think about a banana as though it  
 were a telephone? His point is, if the representational  
 system, which cognitivists claim to underpin cognition, is  
 still in the process of “mapping” the world, how does it  
 manage to tolerate distortions such as this? How is it that  
 our cognition does not “crash” given this arbitrary  
 onslaught? While his own solution to this problem is to  
 propose a meta-representational account of pretence (about

372 which we have more to say in Sect. 4.2), Harris (2000) has  
373 challenged his reasoning.

### 374 3.2 Imagining

375 If children pretend, then adults imagine. Vygotski (1978)  
376 writes that “Imagination is a new formation that is not  
377 present in the consciousness of the very raw young child is  
378 totally absent in animals and represents a specifically  
379 human form of conscious activity.” We have already noted  
380 that imagination is “internalised” pretending or is “pre-  
381 tending without the physical actions”.

382 We have adopted a fairly pragmatic perspective because  
383 imagination and imagination have proved to be highly  
384 resistant to definition. One of the problems with defining,  
385 much less understanding, imagination is that it might rea-  
386 sonably be applied to such activities as day-dreaming,  
387 fantasising, visualising, wishing (and, of course, pretending  
388 and making-believe) and a whole host of other slippery  
389 concepts. Further, the word itself also suggests the  
390 involvement of visual imagery which may or may not exist  
391 as a definitive and distinct mode of representation (e.g.  
392 Pylyshyn 1973, 1981).

393 However, Harris (2000) describes imagination as the  
394 capacity to consider alternative possibilities and their  
395 implication. He also tells us that this emerges early and  
396 transforms children’s developing conception of reality. We  
397 note that his position is quite similar to that explored in this  
398 paper but our terminology is different, and his work is  
399 primarily focussed on child development. Helpfully, he  
400 identifies three roles for imagination (p. 161): (1) to  
401 become “absorbed in make-believe or fictional worlds”;  
402 (2) to make “comparisons between actual outcomes and  
403 various outcomes”; and (3) to explore the “impossible and  
404 magical”. This reference to absorption in make-believe  
405 worlds points clearly at a role for imagination in the  
406 exploration of the magical worlds of digital media.

### 407 3.3 Make-believe

408 So far we have adopted a simple approach to key defini-  
409 tions. Pretending is child’s play, and imagination is inter-  
410 nalised pretending. What of the operation of make-believe?  
411 Here, we follow Walton (1990) and implicate the external  
412 world in make-believe.

413 We propose that pretending and imagining must share  
414 core cognitive resources—one being the “adult” version of  
415 the other and we can also reasonably say that both reflect  
416 our embodiment. Vygotski (1978) (again) telling us, “Like  
417 all functions of consciousness, [imagination] originally  
418 arises from action”. However, both pretending and imag-  
419 ining routinely make use of external artefacts. Walton  
420 (1993) writes “Dolls and hobby horses are valuable for

421 their contribution to make-believe. The same I true for  
422 paintings and novels. These and other propos stimulate our  
423 imagination and provide for exciting or pleasurable or  
424 interesting engagements with fictional worlds. A doll, in  
425 itself just a bundle of rags or moulded plastic, comes alive  
426 in a game of make-believe, providing the participant with  
427 (fictional) baby”. Walton calls this “prop oriented make-  
428 believe” which he contrasts with “content-oriented make-  
429 believe”.

430 Make-believe, in the context of the current discussion, is  
431 of this form though “affordance oriented make-believe”  
432 may be a more cogent description.

## 433 4 Make-believe as cognition

434 It is now well established in both the philosophical and  
435 psychological literature that there are two kinds of think-  
436 ing, one fast and intuitive and the other slow and deliber-  
437 ative (e.g. Epstein 1994; Hammond 1996; Sloman 1996;  
438 Evans and B. T. 2003; amongst many others). Further, this  
439 distinction has not been confined to theoretical consider-  
440 ation alone as these two forms of cognition have been  
441 researched in domains as diverse as judgment and decision  
442 making (Kahneman 2002; Kahneman 2011); learning  
443 (Dienes and Perner 1999; Reber 1993), social cognition  
444 (e.g. Chaiken and Trope 1999; Epstein 1994) and enaction.  
445 For example, Hutto and Myin (2013), from a radical en-  
446 active viewpoint, distinguish between “basic minds” and  
447 “enculturated, scaffolded” minds. The former is responsi-  
448 ble for the “vast sea of what humans do and experience”  
449 while our encultured minds are capable of language, more  
450 speculative thinking and planning.

451 And because of the huge diversity of terms used to  
452 describe these two forms of thinking, it has become  
453 something of a convention to designate them system 1 or  
454 system 2 thinking.

455 System 1 is the form of cognition common to both  
456 humans and other animals. As we have already noted that  
457 its operation is fast and intuitive and is responsible to our  
458 day-to-day coping with the world. System 1 thinking has a  
459 long list of attributes associated with it including being  
460 high capacity, associative, contextualised and not con-  
461 scious. Kahneman (2011) adds to this list “able to complete  
462 the phrase, ‘bread and ...’”, being able to answer the  
463 question, “2 + 2=” and being able to read and understand  
464 simple sentences. In reality is probably not a single system,  
465 but may comprise to be a set of autonomous sub-systems  
466 (e.g. Stanovich and West 2003; Stanovich 2004).

467 Dual-process theorists claim that human beings evolved  
468 a powerful general purpose reasoning system—system 2—  
469 which coexists with our older system 1 abilities. Unlike  
470 system 1, system 2 is slow, has limited capacity and is

471	conscious. System 2 thinking is also uniquely human and	imaginatively, to engage in what “if thinking” and to	522
472	may have evolved quite recently—perhaps within the past	engage in make-believe.	523
473	50,000 years. System 2 thinking is sequential and has a	Given that we are able to engage in two distinct forms of	524
474	relatively limited capacity; it is also slower than system 1	thinking, we must inevitably be able to switch between	525
475	thinking. However, system 2 permits a number of opera-	them. In practice, this means decoupling from the pre-	526
476	tions which are not available to system 1 thinking. These	dominant system 1 thinking which is busy allowing us to	527

508	about 50,000 years ago, when people who looked like us	4.2.2 Possible world boxes	559
509	[...] finally began acting like us.” Although there is some	Nichols and Stich (2005) have created an influential cog-	560
510	debate about the timing of this “overnight flowering”, it is	nitve model of pretending which itself is based on a	561
511	generally agreed that modern humans are capable of	modification to what they describe as the “widely accepted	562
512	(Lewis-Williams 2004, p. 97): abstract thinking; the ability	account of cognition as adopted by people working in this	563
513	to act with reference to abstract concepts; planning depth;	field”. Nichols and Stich make it clear that they do not	564
514	the ability to formulate strategies [...] and to act upon them	believe that their account is necessarily complete or	565
515	in a group context; behavioural, economic and technologi-	definitive but that they do think that they have, in contrast	566
516	cal innovation; and symbolic behaviour, the ability to	to other researchers, described pretending quite fully. Their	567
517	represent objects, people and abstract concepts with arbi-	most frequent criticism of other accounts being that they	568
518	trary symbols. These are some of the many behaviours		
519	which distinguish modern man from our ancestors. It is		
520	plausible to believe that the development of system 2		
521	thinking is the source of these abilities to think		

569 are “under-described”. They begin by noting that the mind  
570 (*sic*) contains two quite different kinds of representational  
571 states, namely, beliefs and desires. Beliefs are what we  
572 know, true and false, about the world. Desires are what we  
573 want, and Nichols and Stich implicate the bodily systems  
574 of being the source of them.

575 To pretend is to create another “world” in the *possible*  
576 *world box* (partition) of our cognition. They tell us that  
577 pretending begins with a premise (“let’s have a tea party”)  
578 which, if adopted by the pretender, forms the basis for sub-  
579 sequent *inference* and *embellishment*. They also recognise  
580 that the premise may be bound or constrained by schematic  
581 structures, writing: “clusters or packets of representations  
582 whose contents constitute ‘scripts’ or paradigms detailing  
583 the way in which certain situations typically unfold” (p. 34).  
584 The contents of the possible world box have full access to our  
585 beliefs and from there to our practical reasoning faculties. An  
586 updater mechanism keeps us informed as to the status of the  
587 pretend episode. The *possible world box* is populated with  
588 representational tokens which are different from those found  
589 in the beliefs and desires boxes. These tokens neither rep-  
590 resent the world as it is, nor what we would like it to be, but  
591 rather represent what the world “would be like given some  
592 set of assumptions that we neither believe to be true (that is,  
593 we believe to be the case) or want to be true” (Nichols and  
594 Stich, *ibid* p. 29). The precise nature of the *possible world*  
595 *box* in their account is, unhappily, a little under-described.

#### 596 4.2.3 Twin Earth

597 Finally, Lillard (2001) rejects the meta-representation  
598 account of pretending and offers the “Twin Earth” model  
599 in its place. The “Twin Earth” model has its origins with  
600 Putnam’s Twin Earth thought experiment.<sup>1</sup> Lillard writes  
601 that pretend play for children is similar to this Twin Earth  
602 thought experiment. She tells us that when children pre-  
603 tend, they create another world that shares many of the  
604 characteristics of the real world. While much remains the  
605 same, there are, of course, significant changes, such as the  
606 “child becomes the mother [and]... sand becomes apple  
607 pie”, (*ibid*, p. 22). Then, the child reasons about the con-  
608 stituent parts of this twin world. Many of the relationships  
609 are unchanged, for example, while the child may pretend to  
610 be the mother; this (twin) mother treats her children just  
611 like the real world version. Lillard notes that both pretend  
612 play and Twin Earth are quarantined worlds which are  
613 *decoupled* from the real world.

1FL01 <sup>1</sup> Putnam’s Twin Earth thought experiment asks us to believe  
1FL02 (pretend) that elsewhere in the universe there is a planet exactly like  
1FL03 Earth in virtually all respects, refer to as “Twin Earth”. Having said  
1FL04 “virtually all respects”, Putnam goes on to propose some differences  
1FL05 between the two for the purpose of philosophical discourse and  
1FL06 exploring the nature of semantics.

614 Although these three models are quite different in detail 614  
615 they appear to be logically very similar. By whatever 615  
616 means we are able to separate ourselves from the real 616  
617 world, and interact with, reason and emote about another. 617

## 618 5 Discussion

619 As film goes we agree to make-believe—at least for the 619  
620 2 h of the movie—that James Bond does not appear to 620  
621 age or suffer from liver disease after several lifetimes of 621  
622 heavy drinking. This is not the suspension of disbelief. 622  
623 No one goes to the cinema muttering under their breath, 623  
624 “I know this is not real but I will suspend this disbelief 624  
625 for the moment”, instead we readily make-believe 625  
626 despite knowing that what we are about to experience is 626  
627 not the case. The movie (game or virtual environment) is 627  
628 brought to life and is made real or real enough, by our 628  
629 ability to make-believe. Making-believe is a form of 629  
630 cognition which is decoupled from the real world and 630  
631 which enables us to explore and engage with fictional or 631  
632 imaginary worlds. If make-believe opens the door to 632  
633 other worlds, then the sense of mediated presence keeps it 633  
634 open. 634

635 This paper has presented a new account of presence 635  
636 which is based on make-believe. It has also proposed that 636  
637 make-believe is a form of system 2 thinking which serves 637  
638 to complement real world presence. We have also argued 638  
639 that the sudden appearance of artistic expression some 639  
640 40,000–50,000 years ago may have coincided with the 640  
641 development of our ability to make-believe. 641

642 Having made a case for make-believe, just what does 642  
643 this tell us about the experience of presence? 643

### 644 5.1 What make-believe tells us about presence

645 Numerous researchers have observed that pretend play 645  
646 shares a pair of features that have labelled *mirroring* and 646  
647 *quarantining*. Indeed, we have already made oblique ref- 647  
648 erence to quarantining already. 648

649 When children pretend, they tend to follow a number of 649  
650 “rules” which are analogues of real world thought and 650  
651 behaviour, and this behaviour been described as *mirroring*. 651  
652 Further, it has also been observed that pretend behaviour is 652  
653 restricted to the bounds of the pretend episode. With a few 653  
654 exceptions, our pretend behaviour is said to be *quarantined* 654  
655 and does not extend into the real world. 655

656 Finally, although mirroring and quarantining govern the 656  
657 behaviour of the pretender, there is also evidence of what 657  
658 we shall describe as “affective-bleed”, or contagion, by 658  
659 which emotional states evoked in make-believe worlds can 659  
660 transfer to the real world. 660

661 We will now consider each of these in turn. 661

662 5.1.1 *Mirroring and quarantining*

663 What is pretended (i.e. the contents of a pretend episode  
664 and the behaviour of those pretending) has been found to  
665 be governed by the same kinds of laws and restriction that  
666 we encounter in the real world. Reality may be suspended,  
667 but not wholly. Make-believe mirrors the real world. We  
668 still expect to hold a make-believe weapon such as a light  
669 sabre in our hands, and we are more likely sitting on the  
670 ruby throne rather than eat lunch off it. These “rules” make  
671 our pretending believable and when they are broken as in a  
672 movie “plot hole” the make-believe becomes unbelievable.

673 **AQ1** Let us consider a tea party again. Leslie (1994) found  
674 that when he “tipped out” and “spilled” the contents of  
675 one of the (empty) teacups, the children regarded this cup  
676 to be “empty” while non-tipped cups continued to be  
677 “full”. The basic laws of physics continue to hold. Walton  
678 (1990) has made similar observations in that make-believe  
679 games, cinema, and a variety of other media are governed  
680 by what he describes as “principles of generation” which  
681 are “reality-oriented”. This *reality principle* is based on  
682 similarities to the real world.

683 He also proposes the *Mutual Belief Principle* for fan-  
684 tastic worlds (the Star Trek™ or Star Wars™ worlds). The  
685 principle is based on a tacit agreement between the creator  
686 of these worlds (and a set of rules which hold for these  
687 fantastic places) and those who experience them. In these  
688 worlds, for example, it is “agreed” that alien languages are  
689 mutually intelligible.

690 Quarantining complements mirroring in that the events  
691 which occurred within the make-believe episode are con-  
692 fined to them. Spilling make-believe “tea” will not result  
693 in clothing really being wet. Perhaps, the most interesting  
694 aspect of quarantining is when it fails. The failure to  
695 quarantine make-believe attitudes, beliefs and behaviours  
696 may be taken to be a symptom of mental illness. This is  
697 evidenced in the all too frequent reports of murderous  
698 gunmen attributing their behaviour to having played vio-  
699 lent games.

700 Thus, the study of make-believe has a good deal to say  
701 about the believability of the experiences offered by digital  
702 technology (please see Turner et al. (in press) for a detailed  
703 discussion of this), and in turn may afford an explanation of  
704 many instances when presence breaks down—where, for  
705 example, fictional premises become too far removed from  
706 the real world or technologies operate in a manner which is  
707 internally inconsistent.

708 5.1.2 *Contagion and affective bleed*

709 Although make-believe is largely governed by mirroring  
710 and quarantining, both may be violated. Quarantining  
711 breaks down and becomes “contagion” when the contents

of the pretence directly affect actual attitudes and behav- 712  
iour. This is most readily witnessed when these attitudes 713  
and behaviour are predominately affective, for example, 714  
imagining something scary (for example, as a fierce animal 715  
in the kitchen) may “bleed” and give rise to actual hesi- 716  
tation such as reluctance to enter the room. 717

In attempting to explain thus Gendler (2008) has pro- 718  
posed a new form of believe—the alief which is “asso- 719  
ciative, action-generating, affect-laden, arational, 720  
automatic, agnostic with respect to its content, shared with 721  
animals, and developmentally and conceptually antecedent 722  
to other cognitive attitudes” (the leading italicised “a’s” 723  
are hers). An alief is also defined as an habitual propensity 724  
to respond automatically and affective to particular stimuli. 725  
So, for example, Gendler also tells us that while a subject 726  
may believe that drinking out of a sterile bedpan is com- 727  
pletely safe, she may nonetheless show hesitation and 728  
disgust at the prospect of doing so because the bedpan 729  
invokes an alief with the content “filthy object, disgusting, 730  
stay away”. By way of further example, Gendler describes 731  
the effect produced by walking on the glass-floored Grand 732  
Canyon Skywalk as an alief incorporating “the visual 733  
appearance as of a cliff, the feeling of fear and the motor 734  
routine of retreat” (2011). This, of course, immediately 735  
recalls Slater’s experiments with the (virtual) visual cliff 736  
(1994) and offers an alternative explanation of his findings. 737  
In these experiments, participants were found to hesitate 738  
when faced with a virtual “pit”. The relevance of conta- 739  
gion to presence research may also some way in explaining 740  
the successful use of virtual reality in the treatment of 741  
phobias (e.g. Rothbaum et al. 1995, 1996; Botella et al. 742  
1998; Emmelkamp et al. 2002). In these instances, virtual 743  
re-creations of spiders, flying, confined spaces and so forth 744  
have been used to systematically de-sensitise those suf- 745  
fering from the corresponding phobias by presenting them 746  
with the object of their fear in a safe, managed environment 747  
but one which is capable of evoking an affective response. 748  
Perhaps, even more dramatically, Hoffman et al. (2006) 749  
have reported the successful use of virtual reality tech- 750  
nology in the pain management of burns treatment. In their 751  
study, they reported that the feeling of cold (induced by a 752  
snowy landscape) can be used to reduce the pain from real 753  
world burns suffered by servicemen. 754

Clearly, at least part of the explanation of the usefulness 755  
of virtual reality in treatment and therapy may lie with the 756  
contagion aspect of make-believe. 757

## 5.2 Further work 758

There are (at least) two areas of further work which 759  
immediately present themselves: the first is the role of 760  
technology in make-believe; the second concerns social 761  
intentionality and social presence. 762

763 To date, developmental psychologists have treated pre-  
764 tending and make-believe as embedded cognitive processes,  
765 that is, confined to the brain. However, there is clearly a case  
766 for artefacts as an essential part in making-believe and to date  
767 this has largely been limited to Walton's remarks as to the  
768 role of the external as prop. One route to elucidating their role  
769 in make-believe, and in turn, presence, would be to adopt an  
770 external cognition perspective following Clark and Chal-  
771 mers (1998) or to adopt a more radical, enactive affordance  
772 only route (*cf.* Hutto and Myin 2013).

773 There is a broad consensus that being able to anticipate  
774 the behaviour and intentions of others is a necessary con-  
775 dition for social relations to exist. This ability is more  
776 usually known as "theory of mind" a term coined by  
777 Premack and Woodruff (1978). We need a theory of mind  
778 to communicate and cooperate with each other and without  
779 it there can be no sense of social presence, the use of  
780 technology to create the experience of being with other  
781 people (e.g. Biocca et al. 2003 and many others). This is a  
782 very broad area of research ranging from the study of the  
783 use of video and text conferencing to the characteristics of  
784 social networking sites and the effectiveness of avatars on  
785 web sites. Biocca and his colleagues (*ibid*, 456–457) define  
786 social presence as the "sense of being with another" where  
787 this other can be either a human or artificial intelligence.  
788 The others to which he refers include representations of  
789 other humans presented by way of text, images, moving  
790 images, avatars and so forth. Predicated on all of these  
791 approaches to "social interaction" is the need for the  
792 ability for one individual to understand the intentions,  
793 motivation and behaviour of others.

794 There is a wide body of research which has demon-  
795 strated clear links between pretend play and a theory of  
796 mind. Pretend play requires the child to be able to coordinate  
797 multiple perspectives i.e. to hold two realities about the  
798 same thing in her mind. Further, when a child sees another  
799 engaged in this same kind of pretending, she must under-  
800 stand (or at least have a theory about) what is going on in  
801 her mind in order to understand the other's pretending.  
802 Social presence, social intentionality and theory of mind  
803 are intimately linked to our ability to make-believe.

804 **Acknowledgments** Thanks to my reviewers for their perceptive and  
805 detailed comments.

## Author Query Form

**Please ensure you fill out your response to the queries raised below and return this form along with your corrections**

Dear Author

During the process of typesetting your article, the following queries have arisen. Please check your typeset proof carefully against the queries listed below and mark the necessary changes either directly on the proof/online grid or in the 'Author's response' area provided below

Query	Details Required	Author's Response
AQ1	References Leslie (1994) and Hoffman et al. (2006) are cited in text but not provided in the reference list. Please provide references in the list or delete these citations.	
AQ2	References Coelho et al. (2006), Gendler (2011), Lillard et al. (2007), Loomis (1992), Stanovich (2006) and Vygotsky (1966) are given in list but not cited in text. Please cite in text or delete from list.	
AQ3	Please provide volume number and page range for the reference Kahneman (2002).	
AQ4	Please provide the page range for the reference Lombard and Ditton (1997).	
AQ5	Please provide complete details for the reference Turner et al.
